C++:

Header Files, Namespaces

Header File - Overview

Break up large files, Speeds compilation process

Organizes code

Separates interface from implementation (and reduces your need to know what goes on 'under the hood')

But adds slight complexity

Header File Rules – 1. YOU MUST USE INCLUDE GUARDS

No include guards you get multiply defined symbols

Instead wrap in an include guard

Upshot:: ALWAYS USE INCLUDE GUARDS ON HEAD

Header File Rules – Just declarations no definitions

```
declaration
In .h file

int a2();
```

```
definition
In .cpp file

int a2(){
    return 2;
}
```

Header File Rules – minimal exposure

In .h file

Only include those files necessary to make header self contained (no compiler errors).

```
#pragma once
//B function definitions
#include <string>

std::string b1();
std::string b2();
std::string b3();
```

In .cpp file

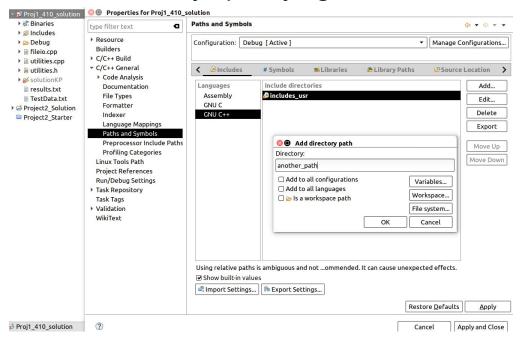

All other includes

Header File General Rules

- <> for system header files
- "" for your header files
- Only const variables (unless part of a class)
- Header file should contain only related stuff
- Never include a .cpp or source file
- Never put a "using namespace ..." declaration in a header file (forces anyone including your header to also use that namespace)
- General strive for complete AND minimal (only what's necessary)

Header Files – Location (eclipse)

- Big projects Organization is key
- Source in one dir, Headers in another
 - Use relative paths (ex. #include "../includes_usr/constants.h"
 - Or let IDE find headers by specifying which directories to search

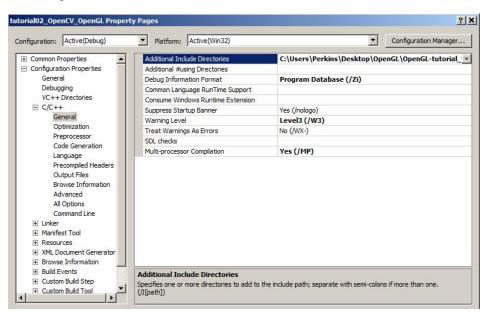

Exercise - Part 1

- 3_refactor_monolithic_file.cpp has a jumble of functions and constants.
- 1. Refactor it into related .h and cpp files.
- Then place all .h files in the folder 'includes_usr'
- 3. Then place utilities.cpp (the function definitions) in the folder 'utilities'

Steps 2 and 3 require relative paths

Header Files – Location (MS VS)

- Big projects Organization is key
- Source in one dir, Headers in another
 - Use relative paths (ex. #include "../includes_usr/constants.h"
 - Let IDE find headers by specifying which directories to search
- VS2012 Properties->C++->General

Namespaces

 Allow grouping code so there are no name conflicts.
 For instance..

 NOTE:must wrap both declaration (.h) and definition (.cpp) with namespace declaration!

```
namespace MySpace1{
                           ms1.h
    void myFunc2();
namespace MySpace2{
                            ms2.h
    void myFunc2();
#include "ms1.h"
#include "ms2.h"
                            main.cpp
int main()
    MySpace1::myFunc2();
    MySpace2::myFunc2();
```

Namespaces

 Explicit scoping. Tell the compiler where to find the declaration. The below says look in std:: namespace for cout and endl declarations.

```
std::cout << "Please enter a filename or \'x\' to exit"<<std::endl;</pre>
```

 Use 'using' construct – tells compiler to look in a particular namespace. Note the lack of std:: below

```
using namespace std;
cout << "Please enter a filename or \'x\' to exit"<<endl;</pre>
```

 There are many namespaces. Wrap your code in namespaces if there is a chance that your functions have the same name as others (encrypt, decrypt, open, close etc...)

Namespaces - std

All C++ standard library constructs live in the std:: namespace

You can open any system include and see that it lives in the std namespace.

```
#include <iostream>
hover over <iostream> and click f3 to open it

#include <ostream>
#include <ostream>
#include <ostream>
#include <istream>
#include <istream>
#include <istream>
#include <istream>
#include <ostream>
#in
```

So always scope these constructs to the std:: namespace

Exercise - Part 2

- 3_refactor_monolithic_file.cpp project
- 1. Refactor to use namespaces (both constants.h and utilities.cpp and .h)
